

## Optimal central bank design: Benchmarks for the ECB

Helge Berger

Received: 2 March 2006 / Revised: 6 March 2006 / Accepted: 3 March 2006  
© Springer Science + Business Media, LLC 2006

**Abstract** The paper discusses key elements of optimal central bank design and applies its findings to the Eurosystem. A particular focus is on the size of monetary policy committees, the degree of centralization, and the representation of relative economic size in the voting rights of regional (or sectoral) interests. Broad benchmarks for the optimal design of monetary policy committees are derived, combining relevant theoretical arguments with available empirical evidence. A new indicator compares the mismatch of relative regional economic size and voting rights in the monetary policy committees of the US Fed, the pre-1999 German Bundesbank, and the ECB over time. Based on these benchmarks, there seems to be room to improve the organization of the ECB Governing Board and current plans for reform.

### 1 Introduction

The institutional underpinnings of decision-making in monetary policy show a considerable amount of time-path dependency or persistence—and for most purposes this is a good thing. Well-defined rules about who gets to decide about interest rates and in what form are commonly thought of as hallmarks of central bank independence, which most observers hold to be a key ingredient for price stability. And indeed, once economic agents and markets have settled on a view of

and CESifo

the institutional set up of a central bank, changing the rules of the game may be risky.<sup>1</sup>

Notwithstanding this persistence, remarkable changes in central bank organization do occur. Prominent examples include the early history of the U.S. Federal Reserve System (Fed) until the 1930s, the reshaping of the Bundesbank after German unification in 1992, or the granting of independence to the Swedish Riksbank and the Bank of England in the late 1990s. Moreover, the 1990s were also a period in which a large number of central banks were founded (or restituted) in transition economies, some of which continued to adjust (or still are in the process of adjusting) their institutional framework to meet the requirements of European Union (EU) (1997) and euro area membership. A final example is the founding of the European Central Bank (ECB) itself and recent organizational changes of the ECB statute in anticipation of the enlargement of the European Economic and Monetary Union (EMU).

The reasons behind observed changes in the decision-making framework for monetary policy vary, but jointly they put a spotlight on the question exactly what we should be looking for in optimal central bank design from an economic perspective.<sup>2</sup> While central bank design has many dimensions, three basic issues stand out: first, how many people should be responsible for monetary policy decisions? Second, how much weight should be given to central vs. regional (or sectoral) representation in decision-making? And, third, should regions (or sectors) be represented according to their economic weight? These questions are more than just of theoretical interest; they were also very much at the center of debate when EMU enlargement forced a discussion of ECB reform.<sup>3</sup>

The present paper will address these questions from an economic perspective, drawing on a still growing literature on optimal central bank design addressing these (or related) issues. As to *size*, Gerlach-Kristen (2006) argues that multiple-member committees handle information processing better than individuals, which suggests efficient decision-making is best handled by groups. Experimental evidence supports this view (Blinder & Morgan, 2005; Lombardelli et al., 2005).<sup>4</sup>

---

<sup>1</sup> In principle, this point extends to changes in monetary policy strategy—for instance, the recent discussion about the pros and cons of moving the U.S. Federal Reserve closer to an inflation targeting framework in the post-Greenspan era (see, e.g., Faust & Henderson, 2004). However, in what follows the focus remains on the decision-making framework. Berger et al. (2001) provide a recent survey on central bank independence in general.

<sup>2</sup> This is not to say that actual central bank design does not also reflect political-economic forces. However, in what follows the focus will be mostly on guidelines for efficient central bank design and, thus economic arguments.

<sup>3</sup> The details of the 2003 ECB reform have been discussed extensively elsewhere—in what follows, we will focus on some relevant aspects of the reform. For a more extensive analysis of the issues involved see, among others, Hefeker (2002), Berger (2002), Dvorsky and Lindner (2003), Meade (2003), Berger et al. (2004), de Haan et al. (2004).

<sup>4</sup> Gersbach and Hahn (2001) look at related issues focusing on transparency. For an overview see Gerling et al. (2005) and Fujiki (2005). Sibert (2006) provides a comprehensive survey over a related—and highly useful—social psychology literature that looks at the effects of group size on information processing and moderation.

Regarding *centralization*, von Hagen and Süppel (1994) and Lohmann (1998) discuss the trade-offs involved in organizing a monetary policy committee as a more or less centralized institution, arguing that, as a rule, a strong representation of regional interest in the Council leads to inefficiencies in policy making.<sup>5</sup> Lohmann's (1997) results suggest that increasing the number of votes of regional central bank governors compared to centrally appointed Board members may result in unwanted monetary policy volatility because it increases the frequency at which the median voter position changes in the policy committee. On the other hand, the results in Moser (1999) and Hallerberg (2002) imply that one advantage of regional representation, if going along with regional powers being involved in defining the central bank's legal setup, can foster the institutions political independence by adding further veto players on the legislative side. Goodfriend (2000), Berger (2002), and Maier et al. (2003) provide yet another argument in favor of limited centralization, suggesting that economic information is mostly regional in nature, and having regional representatives within the Council could enhance the precision with which economic data is perceived and analyzed. Finally, Hefeker (2003) argues that a central bank's design will, in part, depend on the economic heterogeneity of the economic area it represents. In particular, a decision-making setup that gives much weight to regional interests can be expected in a country that exhibits considerable divergences in terms of economic structure and preferences. In this case, regional political powers are likely to resist delegation of monetary policy to a centrally appointed board that focuses its decisions on the (weighted) average of economic developments in the currency area and might have different preferences than the regions.

A third group of relevant papers is related to the question of *representation*. These papers take the size of the Governing Council and a (less than full) degree of centralization as given, and ask how to deal with shocks to national preferences within such a federal central bank system. Waller and Walsh (1996) suggest overlapping contracts for monetary policy committee members as an institutional device to moderate the impact of regional preference shocks—a point also stressed by Lindner (2000). Gersbach and Pacht (2004) propose flexible majority rules for committee decisions, raising majority requirements for policy proposals (motivated, for instance, by idiosyncratic national shocks) in line with the size of the desired interest rate change. The advantages of alternative decision-making arrangements, including simple majority voting, are also discussed in Bullard and Waller (2004) within a general equilibrium framework. Heisenberg (2003) favors increasing the transparency of committee decisions to reduce incentives for regionally biased policies (see also Gersbach & Hahn, 2001). Finally, Berger and Müller (2004) show that over- or underrepresentation of economic size through asymmetric voting weights or rotation schemes can be helpful to moderate the impact of regional preference shocks on a monetary policy aimed at stabilizing output and inflation in a currency union overall.

In addition to exploring core arguments regarding optimal size, centralization, and representation in central bank design, the present paper adds an empirical

---

<sup>5</sup> Throughout the paper, the term “regional” will refer to the jurisdictional level represented in the monetary policy committee in addition to Board members. Thus, in case of the Fed, “regional” will imply the states, in case of the ECB, the countries or nations forming the union.

perspective regarding the size and structure of monetary policy committees. Empirical perspective, in addition to illuminating the sometimes surprising variety in the way central banks are set up, provides orientation regarding more common (and, thus, perhaps more workable) solutions to some of the trade-offs that theory can describe but (for the most part) not decide.

The remainder of the paper is organized as follows. Section 2 will highlight the basic central bank design problem and develop broad benchmarks for monetary policy committees. Section 3 will apply these benchmarks to the Eurosystem before and after euro area enlargement. Section 4 concludes.

## 2 The Basic Design Problem

The question of central bank design has many dimensions, both theoretically and empirically. In recent years, the theoretical debate has focused on a wide range of topics, from the question of transparency or communication to the virtues of inflation targeting, among other things. At the same time, European policy makers debated the pros and cons of topics such as central bank involvement in financial supervision, a Lender-of-Last-Resort function for the ECB, or its role in organizing real-time settlement systems within Europe. In what follows, however, the focus will be on the way a central bank should organize the way it reaches decisions on monetary policy.

### 2.1 Size: How Many People Should Be Responsible For Monetary Policy Decisions

Without doubt, size, that is, the number of people explicitly or implicitly involved in monetary policy decisions, is among the more important dimensions of central bank design.<sup>6</sup> There are costs and benefits of a larger committee. As to the *benefits*, Gerlach-Kristen (2006) shows that multiple-member committees are better able to form a view on the state of the economy than a single individual that relies mostly on his or her own information and judgment. Faced with an uncertain environment—for instance, regarding the current or expected levels of the output gap—committee members can pool individual information, cooperate in information processing, or give more productive members a larger relative weight in the process. As a rule, this will lead to better informed decision making.<sup>7</sup>

---

<sup>6</sup> An important issue excluded here is the question of exactly *how* members are (in whatever function) selected into the MPC, raising important questions of transparency and possible political bias. Waller (1989, 1992, 2002) discusses important elements of the broader topic of central bank appointments. A related literature, which is also not highlighted above, deals with conflicts between sectors or vested interest groups within committees—see, for instance, Herrendorf and Neumann (2003).

<sup>7</sup> Berk and Bierut (2004), too, argue that a systematic exchange of views within monetary policy committees will be beneficial because it tends to improve the quality of decision-making without necessarily resulting in dependent voting behavior. As already mentioned, Gerling et al. (2005) and Fujiki (2005) provide recent surveys of the emerging literature of decision-making in committees.

Blinder and Morgan (2005) and Lombardelli et al. (2005) second this argument based on empirical result from experiments. A related argument is that a larger monetary policy committee may keep policy from going to extremes (Blinder, 1998).<sup>8</sup> One is tempted to add that slowing down the decision-making process by means of increasing committee membership may also be a way to overcome what the theoretical literature has dubbed the stabilization bias of monetary policy (e.g., Woodford, 2003)—but, clearly, there must be more efficient ways of introducing optimal inertia into interest rate setting.<sup>9</sup>

On the *cost* side, there is reason to believe that decision-making costs increase in committee size. While the arguments below leave little doubt that, overall, larger decision-making bodies and the resulting high decision-making costs are a disadvantage from an efficiency point of view, the issue is slightly less clear cut than it appears at first glance. For instance, Blinder and Morgan (2005) argue that, at least to a degree, small groups of individuals may be able to reach a decision at a speed broadly comparable to an individual. It seems doubtful, however, whether this extends to larger committees of the order of magnitude relevant for the ECB or Fed.

One important aspect is communication. Even if the exchange of ideas is limited to short introductory statements by each member, larger committees will easily spend considerable time just taking note of positions. In addition, actual decision-making costs are likely to have a non-linear component. For instance, if there is a need or tradition to “sound each other out” bilaterally before or during committee meetings, the time required to prepare a decision grows non-linearly in the number of members.<sup>10</sup> Moreover, if diversity of opinion is increasing in the number of committee members, reaching an agreement might require more effort by all involved. Richard Baldwin (2001) aims in this direction, when he (somewhat exaggeratingly) suggests that—in the absence of reform—euro area enlargement will leave the ECB Governing Council with “too many [members] to decide on where to go to dinner, let alone agree on how to run monetary policy for more than 400 m people...”

To illustrate, consider a monetary policy committee that prepares decisions through (i) a series of pre-meeting bilateral negotiations, during which each member interacts with each other member, and (ii) a “tour d’horizon,” a short intervention by each member during the actual committee meeting. Assume further that both actions require a similar effort. Then the overall preparatory effort, that is, decision-making costs,  $C$ , of the committee would be

$$C(n, e) = n(n + 1) \frac{e}{2},$$

<sup>8</sup> A more recent contribution pointing in the same direction is Riboni and Ruge-Murcia (2006).

<sup>9</sup> For instance, Mirzoev (2004) argues that lowering the meeting frequency of monetary policy committees might be helpful in this regard by providing a commitment to hold policy decisions constant for a period of time.

<sup>10</sup> Barber (2001) argues that bilateral meetings are a relevant practice in the ECB.

**Fig. 1** Decision-making costs: An illustration

with  $e$  measuring effort (and/or time) and  $n$  the number of committee members.<sup>11</sup> Figure 1 depicts the exponential form of the cost function for two alternative values of  $e$ .

For instance, if effort was measured in minutes spent on decision-making and only 5 min were required for each “tour d’horizon” and bilateral discussion ( $e = 5$ ), a committee of nine would spend about 4 h, a committee of 18 about 14 h, and a committee of 27 more than 30 h preparing a decision—no small amount of time when speed is of the essence.

For a given number of committee members, decision-making costs are also influenced by the particular way or mechanism decisions are reached. For instance, about half the close to 90 central banks surveyed by Fry et al. (2000)—including the Fed and the ECB—seem to follow a consensus-oriented approach. This approach requires all monetary policy committee members to verbally agree on a certain decision before a vote is called. Arguably, finding a consensus will take more time and effort and, thus, imply higher decision-making costs than a simple voting rule.<sup>12</sup> This could be because under a strict voting rule some of the decision-making costs discussed above would not accrue (policies would simply be proposed and voted upon without prior consultation or exchange of statements) or

<sup>11</sup> If  $n$  is the number of committee members, the number of bilateral discussions is  $\frac{1}{2} n(n-1)$ .

<sup>12</sup> These costs can be mitigated by leadership, for instance because the Board initiates and prepares many committee decisions (e.g., von Hagen & Brückner, 2001), but surely that leadership ability, too, will face greater challenges as the number of committee members increases. Baldwin et al. (2001) argue, for instance, that EMU enlargement might make it more difficult for the ECB Board to find sufficient support for monetary policy measures with a proper euro area perspective. See Blinder and Wyplosz (2004) for a “typology” of monetary policy committees based on the degree of internal leadership.

because no additional time and effort would be spent on consensus finding and bargaining during the meeting.<sup>13</sup>

On the other hand, simple voting mechanisms—despite their possible advantages regarding decision-making costs—may have disadvantages regarding the quality of decisions. For instance, Gerlach-Kristen (2006) shows formally that optimal signal extraction procedures might deviate from simpler mechanisms, including averaging the available information or majority voting on it (i.e., using the median rather than the mean), if committee members are not equally skilled in processing information.<sup>14</sup> In a broadly related vein, Gersbach and Pachtl (2004) argue that, if preferences of decision makers have an unwanted regional bias, conventional majority rules might lead to inferior policy outcomes compared to more elaborate voting rules. They show, for example, that monetary policy would be less likely to be biased by regional considerations if majority requirements were a positive function of the size of the desired interest rate change. One implication of this type of argument is that the presence of non-voting decision-making procedures in policy committees may well be efficient in information terms. As a consequence, it would be hard to argue in favor of voting-based procedures on the basis of lower decision-making costs alone.<sup>15</sup> Whatever the procedure, however, the question remains, how large the monetary policy committee should be.

Weighing costs and benefits, the optimal size of a monetary policy committee is likely to be a moderately large number. While the information-related arguments on the benefit side suggest that single-person committees are not efficient, the overall number of participants should remain limited in the presence of exponentially increasing decision-making costs. The question remains what exactly “moderately large” means. In the absence of systematic empirical work linking the size of monetary policy committees to the achievement of policy targets, it is at least informative to note that the average size of committees is clearly larger than one and seems to be closer around ten than 20 (Lybeck & Morris, 2004). The upper panel of Table 1 shows the distribution of central bank governing bodies

---

<sup>13</sup> The difference between consensus-based and vote-based approaches may be even larger, if there was a difference in the number of voting and non-voting members. For instance, there are 19 members that participate in the Fed’s FOMC meetings—all seven Board members plus the 12 regional Fed presidents—but at any given meeting only five out of 12 regional representatives hold a right to vote. If, as already indicated, the FOMC indeed reached decisions by consensus, all members would be involved and decision-making costs are likely to be significantly higher than under a simple majority rule voting procedure that would effectively exclude non-voting members. The same applies to the ECB’s Governing Council once more that 15 national central bank governors participate in Governing Council meetings, with only 15 voting rights rotating among them following the 2003 ECB reform (Servais, 2006).

<sup>14</sup> This suggests the possibility of free-riding: if processing information is individually costly, there might be incentives to hope that other committee members provide the public good. This mechanism would add to the cost of increasing membership size (Sibert, 2006). Fry et al. (2000: 129), too, stress that informational aspects should limit the maximum size of the “ideal” monetary policy committee.

<sup>15</sup> Another problem with such a recommendation would be that it might all but impossible to force a committee *not* to prepare a voting decision through more or less intensive preparatory communication and negotiation.

**Table 1** Number of members in governing bodies 2003

(a) Distribution						
	Distribution of members (in percent)					Obs.
	1–3	4–6	7–9	10–12	≥13

Bank (Federal)	Number	Bank (Central)	Number
Bundesbank pre-1957	10	Australia	9
Bundesbank 1998	17	Canada	7
Fed	12 (19) <sup>a</sup>	New Zealand	1
ECB (2001)	18	Sweden	6
ECB (EMU24) <sup>b</sup>	21 (30) <sup>a</sup>	UK	9

Source: Lybek and Morris (2004) and Berger (2002).

<sup>a</sup> The FOMC has 12 voting members, but there are 19 regular members participating in discussion and consensus-finding. Taking into account the ECB reform of 2003, the ECB Governing Council would have 21 voting members and 30 members overall if euro area membership increased to a hypothetical 24 (see below).

<sup>b</sup> “EMU24,” an arbitrary example, could comprise the current 12 members plus the ten recent EU entries, as well as Bulgaria and Rumania.

that are concerned with setting policy goals (about 50 out of 95 countries surveyed in the sample) as well as the distribution of bodies implementing and/or deciding monetary policy. The data do not allow computing means, but the median in both categories falls into the 7–9 and 10–12 member range, respectively. The median monetary policy committee surveyed by Fry et al. (2000) has 5–10 members.

The information in the lower panel of Table 1 lists (somewhat more precise) information on the size of monetary policy committees for selected developed economies, with interesting implications for the ECB. The table suggests that the ECB’s Governing Council, with currently 18 voting members is among the larger ones (even) in this sub-sample, comparable only to the Fed’s FOMC or the pre-1999 Zentralbankrat of the German Bundesbank. As a rule, centralized central banks operate under smaller monetary policy committees closer to the median values found in the upper panel of Table 1. If, however, euro area membership were to increase from today’s 12 to 24 members—a likely scenario, with, for instance, the eventual entrance of the ten new EU member countries as well as likely future candidates such as Rumania and Bulgaria—the Council would comprise 30 members.

The size of the ECB Governing Council will remain problematic even after the 2003 reform of the ECB statute. The reform will limit the number of voting seats of national representatives to 15 and freeze the number of voting Board members at six, restricting the maximum number of voting members to 21 in any reform scenario (ECB, 2003; Servais, 2006). However, if all members present at Governing Council meetings de facto continued to participate in a consensus-based decision-making process, decision-making costs would still be likely to be significantly higher

than in most other central banks, including federal central bank systems.<sup>16</sup> In this regard it is interesting to note that both the Bundesbank and the Fed reduced the size of their decision-making bodies over time (Berger, 2002). As Meltzer (2004) and Eichengreen (1992) illustrate, the present statute of the Fed's FOMC is the outcome of a historical process determined, among other things, by efficiency concerns. And one of the purposes of the German Bundesbank reform of 1992 was preventing an increase in the size of the Zentralbankrat German unification would have demanded. Before 1992, each German Land had a representative in the committee, and without reform, membership would have exceeded 22—a number that, according to the Bundesbank, “would have greatly complicated that body's decision-making processes” (Deutsche Bundesbank, 1992: 50).

## 2.2 Centralization: How Much Weight for Regional (or Sectoral) Representation?

Given the size of the monetary policy committee, another relevant design problem is the degree of centralization—that is, the relative number of seats allocated to members nominated by regional (or sectoral) and central authorities. In the case of the ECB's Governing Council or the Fed's FOMC, for instance, this means to decide on the share of Board seats.

In part, the answer hinges on certain assumptions about the heterogeneity of regions and the focus of local representatives. The question of centralization would be mute, if regional representatives' preferences were identical and regions did not differ in terms of economic structure and economic development, or if they focused not on regional issues but solely on the aggregate well-being of the currency area.<sup>17</sup> Over- or under-representation of economic weight matters, however, if there is a chance that regions differ in economic terms or that their representatives in the monetary policy committee show differences in policy priorities or signs of a ‘home bias.’ We will return to the issue of ‘home bias’ and diverse references below. Regarding regional economic heterogeneity, it is probably safe to assume that some of the surprisingly persistent differences in economic developments in particular within the euro area (and also, to a degree, within the US) will continue to pose challenges to aggregate monetary policy in the foreseeable future.<sup>18</sup>

The argument on the *benefits* of centralization has more than one aspect, but the general idea is that strong regional (or sectoral) representation in the monetary

---

<sup>16</sup> Remarkably, this view is shared, in part, by the ECB (2003: 83): “[Th]e participation of *all* [emphasis in original] governors at the meetings of the Governing Council will not necessarily make deliberations easier...” The ECB stresses, however, that “...the new voting system clearly enhances the efficiency of decision-taking.” (ibid.).

<sup>17</sup> Baldwin et al. (2001: 30) echo an opinion often heard among central bank watchers when they write that, in principle, “the homogeneity of American states suggests that regional representatives on the Fed are less likely to have a regional perspective than would European regional representatives.” Thus, a regional perspective in itself might be unproblematic as long as the regional heterogeneity is low enough.

<sup>18</sup> See, for instance, de Haan et al. (2004) for a survey of the empirical literature. Giannone and Reichlin (2005) provide a very recent discussion of the relative economic diversity of the euro area.

policy committee might lead to inefficiencies at the aggregate level.<sup>19</sup> A first approach leading to this conclusion focuses on preferences. For instance, assuming partisan preferences over monetary policy, Lohmann (1997) argues that a centralized committee, with relative fewer members appointed at the regional level, will see fewer changes of the committee's median voter and, as a consequence, a less volatile monetary policy. Another starting point is the possible presence of a regional bias in decision making of regionally appointed committee members (von Hagen and Süppel, 1994).<sup>20</sup> To take an extreme case, assume that regional representatives focus solely on local developments while the central bank's legally defined responsibility is to ensure that an area-wide target is reached. A relevant example is the Maastricht Treaty that defines the ECB's goals as price stability based on the harmonized euro area CPI index (HCPI), computed by Eurostat as the properly weighted average of regional HCPI indices. If regionally appointed members have a regional focus and ignore the aggregate, monetary policy could deviate from that ideal.<sup>21</sup> Thus, one benefit of increasing the relative number of centrally appointed members in a monetary policy committee could be the absence of a regional bias in decision making.

The notion of a 'home bias' of regionally appointed committee members is not completely implausible. Even though, for example, the ECB (1999: 55) stresses that all members of the Governing Council act in "a fully independent personal capacity" and not as "national representatives," regional economic considerations might indeed inform the behavior of governors in the Council. This assumption is certainly popular with the academic literature (see, among others, Lindner, 2000; Aksoy et al., 2002; Gros & Hefeker, 2002; Gersbach & Pacht, 2004; and Frey, 2004) as well as the media. For instance, *The Economist* (1998) stated with regard to the ECB that "[t]he Governing Council is supposed to set interest rates according to conditions in the euro area as a whole, but there is a risk that national governors will be unduly influenced by conditions in their home country.... A weak center, combined with strong national interests, could create conflicts that undermine the whole system's credibility."

What is more, there is empirical evidence of regional influences in federal central bank systems. Meade and Sheets (2005, 2006) document and analyze FOMC voting patterns since the late 1960s and show that decision makers, in addition to aggregate concerns, take into account regional factors when casting votes on monetary policy.<sup>22</sup> Meade and Sheets also find that, as a rule, regional Fed bank presidents have been more likely to dissent from the FOMC's majority vote than Board members. Berger and de Haan (2002) provide comparable

<sup>19</sup> For the sake of brevity, in what follows, the focus will be on regional representation alone.

<sup>20</sup> Conclusions broadly along this line were prominently featured in a number of papers written prior to the establishment of the ECB. See, among others, Lohmann (1998).

<sup>21</sup> There is an implicit assumption that the decision-making mechanism does not implicitly or explicitly weigh individual opinion in a way that leads to policies compatible with the aggregate target—we will return to this issue in Section 2.3.

<sup>22</sup> Earlier work on FOMC voting includes Havrilevsky and Gildea (1995), and Tootell (1991). Heinemann and Huefner (2004) and Meade and Sheets (2005) argue that there might even be indications of regional voting behavior in actual ECB policy. Chappell et al. (2005) provide an extensive analysis of political-economic influences on individual voting behavior in the FOMC.

evidence for the voting behavior of regional central bank governors in the Bundesbank's Zentralbankrat. They show that the probability of a regional representative to vote against the majority vote increased in the difference between their respective regional and national economic developments, in particular inflation and real GDP growth.

There are, however, also *costs* associated with decreasing the vote share of regional representatives in the monetary policy committee. One argument in favor of a strong regional presence rests on checks and balances. If the power to nominate committee members is shared among, say, federal and regional governments, it is less likely that monetary policy will be influenced by the political whims of either level of government, leading to a higher factual independence.<sup>23</sup> The logic is borrowed from Moser (1999), who stresses the advantage of additional legislative veto players for the central bank's institutional independence (see also Hallerberg, 2002). The Bundesbank seemed to support this view, when it called the continued presence of regional governors in the Zentralbankrat after the 1992 reform an "important element in the Bundesbank's ...independence" (Bundesbank, 1992: 49–50).

A second cost factor associated with increasing degrees of centralization may be loss of information. As pointed out by Goodfriend (2000), much of the information relevant for monetary policy originates at the regional level, and a good understanding of regional developments is of special importance in diverse economic environments such as federal currency unions. Therefore, a strong regional presence in the monetary policy committee will have its advantages also from an informational perspective (Berger, 2002). Maier et al. (2003) provide an interesting formalization of the argument.<sup>24</sup> A similar argument could be made regarding differences in transmission mechanisms of monetary policy (Gros & Hefeker, 2002; Benigno, 2004).

What does this imply for the *optimal degree of centralization*? While the discussion so far seems to favor an intermediate solution, real world monetary policy committees tend toward the extreme. Table 2 (upper panel) shows that—based on the Lybeck and Morris (2004) data—the vast majority of central bank governing bodies is fully centralized. Only 8% of the governing bodies concerned with setting policy goals and only 7% of the bodies in charge of policy implementation have members representing regional or sectoral interest.

While most central banks laws stipulate no regional representation, those representing large federal systems or currency unions provide most of the exceptions, perhaps reflecting the greater economic and political heterogeneity compared to areas governed by more centralized central banks. Indeed, Alesina and Spolaore (2003) argue that there is a positive relation between the size (in terms of population) of a regional entity and the heterogeneity in preferences within its borders, and similar regularities might be at play regarding economic

---

<sup>23</sup> We will return to a similar argument when we discuss the issue of representation of economic size.

<sup>24</sup> Hefeker (2003) makes a related point—albeit from a political-economic perspective. He argues that regional authorities might resist a centralized design of a common central bank if their policy preferences differ from Board members and the local economy's economic structure deviates significantly from the average in the currency area.

Notes: Numbers without (with) parentheses indicate voting (non-voting) membership. See footnotes to Table 1 for details.

diversity.<sup>25</sup> Looking at the examples selected for in the lower panel of Table 2, Germany, the US, and the euro area all fall into this category.<sup>26</sup>

However, even if we restrict the comparison to the US and Germany, the ECB shows the smallest degree of centralization. Focusing, first, on the distribution of voting rights, we find that the weight attached to regional representatives in the Bundesbank's Zentralbankrat and Fed's FOMC, at about 53 and 42%, respectively, is much lower than in the current ECB Governing Council, where regional governors hold about 67% of votes. This gap is bound to increase as EMU membership increases. In the hypothetical euro area with 24 members introduced earlier (see Table 1), the political weight of regional governors rises to about 71% despite the 2003 reform of the ECB statute. Looking instead at total monetary policy committee membership including non-voting governors, the differences

<sup>25</sup> Strictly speaking, Alesina and Spolaore (2003) are concerned with the size of nations—but the argument readily extends to trans-national bodies such as EMU. Rose (2005) provides some empirical evidence on the issue.

<sup>26</sup> Others are Switzerland and Tanzania. See Lybek and Morris (2004).

remain stark. At about 62%, the overall share of regional members in the FOMC is in the vicinity of today's ECB, but the ECB's figure would increase to 80%, if euro area membership increased to 24.

### 2.3 Representation: Should Regions be Represented According To Size?

Taking the size of the monetary policy committee and a certain degree of centralization as given, the question is whether the voting rights of regional governors (or their otherwise defined political clout within the committee) should be in line with the economic weight of the region they represent. In other words, should the committee be organized along what could be called the "one region, one vote principle?" As with centralization, the answer depends on the heterogeneity of regions and the focus of local representatives. In what follows, we will continue to assume that regions may differ in economic as well as preference terms and that their representatives show signs of a 'home bias.'

Under these assumptions, an obvious *cost* associated with the misrepresentation of economic size is that committee decisions might deviate from the first-best, defined as the policy a decision-maker looking at the properly weighted area average would have chosen. This would be particularly worrisome if, for example, a large region underrepresented in the monetary policy committee was characterized by a systematically more volatile (or less volatile) business cycle than other regions. Or consider the case of a small region being overrepresented in the monetary policy committee with inflation below the weighted inflation average or the currency union. In this case, a majority of committee members might favor a more expansionary policy stance than a single decision-maker focused on the aggregate. To avoid regional bias in monetary policy, the optimal voting weight of a given regional representative should exactly match the represented region's economic weight. With perfect representation, committee decisions would replicate the decisions of a single decision maker focused on the aggregate.<sup>27</sup>

Another issue could be accountability and credibility. Focusing on the euro area, Servais (2006) points out that economic agents and politicians might simply not be content with a majority of small countries running monetary policy, leading to a credibility loss for the common central bank. This view is supported by Fahrholz and Mohl (2004: 1), who argue that "considerable loss of current EMU-members' influence power especially in favour of joining Central Eastern European Countries (CEECs) results in a loss of monetary credibility of the ECB: as transparency of the decision-making process within the ECB is lacking,

---

<sup>27</sup> This is also true if monetary policy decisions are based on a bargaining approach as long as voting rights influence fall-back positions. See Berger (2002) for a formalization of the argument. See Bindseil (2001), Baldwin et al. (2001) and Fahrholz and Mohl (2004), among others, for a related discussion that takes into account coalition building. While the basic message stemming from this kind of analysis generally follows the gist of argument in the main text, there are differences. For instance, using the concept of a Banzhaf power index, Fahrholz and Mohl (2004) show that, under certain conditions, the ECB reform could actually amplify problems of misrepresentation compared to the pre-reform status quo.

markets may consider the ECB to be too much inclined to the economic performances of the CEECs.”

But there might also be *benefits* from misrepresenting economic size. One argument in support of the “one region, one vote principle” is political stability (Berger, 2002). Assume, for the sake of the argument, that regional representatives’ policy preferences—e.g., their preferred inflation target or their views on the relative priorities of inflation and real policy goals—are subject to shocks of similar volatility. Then a more equal distribution of voting rights regardless of economic size can help to mitigate the aggregate impact of these shocks by allowing regional preference shocks to offset each other, thereby moderating unwanted volatility of monetary policy decisions at the union level. Of course, if preference shocks differ in variance across regions, moderating the impact at the aggregate level would require a more asymmetric distribution of voting rights, but still one that would be independent of relative economic size.

This leaves us with the question of the *optimal degree of representation* of economic size. Some insight can be gained from the formal discussion of the trade-offs involved. Berger and Müller (2004) model the advantages of moderating regional preference shocks at the aggregate level (through a distribution of voting weights in line with the relative stability of preferences) and the benefits from preventing regional interests distorting monetary policy in the face of national or regional economic shocks (through conditioning voting weights on relative economic size). Optimal regional representation reflects economic size and the stochastic properties of economic and preference shocks. As a rule, “one region, one vote” will not be optimal, but neither will be a perfect alignment of voting rights and relative economic size. Under plausible conditions, the formal exposition supports some over-representation of relative smaller countries.<sup>28</sup>

How regional governors are represented within the ECB’s Governing Council and how does this compare to other federal central banks? Providing a partial answer, Fig. 2 compares the relative economic size of current euro area members with the voting power allocated to the governors representing these members (upper panel). The lower panel provides the same information for the hypothetical EMU with 24 members taking into account the 2003 ECB reform. The reform, in addition to limiting the number of national central bank governors to 15, introduces an asymmetric rotation scheme organizing the way governors will exercise these voting rights once EMU membership exceeds the number of votes (ECB, 2003). As euro area membership increases, governors will be divided into two and then three groups out of which they rotate into a limited number of voting seats. Country representatives will be allocated to groups by size, and groups encompassing larger countries hold more voting rights in the Governing Council.<sup>29</sup>

<sup>28</sup> Reflecting the argument made above regarding the cost of misrepresentation, an increase in economic volatility will reduce the gap between relative economic size and optimal representation of a region (lowering the weight an overrepresented region receives and increasing the weight of underrepresented ones), while an increase in the volatility of preference shocks unambiguously lowers optimal representation.

<sup>29</sup> Size is being measured by a so-called composite indicator that takes into account both relative GDP and financial market size. See, among others, Berger et al. (2004) for additional discussion of this aspect.

**Fig. 2** Distribution of voting rights and economic size in EMU

Source: ECB, IFS, and own calculations.  
 Note: Relative size based on GDP.

Obviously, there are stark differences between the relative economic might of regions (or countries) and the way these regional interests are represented in the ECB’s Governing Council in terms of voting weights. Under the “one region, one vote” rule—formally known as the “one person, one vote” principle—seven out of 12 member countries hold voting power in excess of their economic weight. After enlargement, taking the hypothetical EMU 24 scenario as an example, this discrepancy will be even larger. Despite the rotation scheme favoring economically larger countries, as many as 20 out of 24 members may be over-represented in term of relative economic size. It is, thus, not entirely implausible that, occasionally, an economic minority will decide monetary policy for the whole of EMU.

The question that Fig. 2 cannot answer is whether the ECB is indeed an outlier with regard to the degree of misrepresentation—after all, misrepresentation in the

**Fig. 3** Misrepresentation of Economic Size. Source: US Census Bureau, US Bureau of Economic Analysis, US Federal Reserve; German Statistical office, German Bundesbank, Meltzer (2003), and own calculations.

Notes: The misrepresentation index measures the sum of the squared difference between regional vote shares in the monetary policy committee and relative economic size in a given year. Absent institutional reform, the data is updated in 10-year intervals. In case of the Federal Reserve, economic size is proxied by population shares until 1977 and GSP shares thereafter. Original population and GSP data are by state and are converted into Fed-districts on a county-by-county basis. (See main text and [Appendix](#) for a discussion of the role of the Board until the 1930s.) In the case of the Bundesbank and ECB, relative GDP shares are used. In all three cases the regional vote share is computed as the sum of the vote share of the region's representative (president or governor) in the monetary policy committee *plus* the region's economic weight times the Board's vote share. The assumption behind the latter is that the weight that the Board attaches to developments in each region is strictly proportional to their relative economic size. However, relative results remain qualitatively similar under alternative assumptions about Board behavior—see Table 3.

(pre-1999) Bundesbank or the US Federal Reserve System might be just as sizable.<sup>30</sup> Figure 3 provides some perspective.

Figure 3 shows time series for the sum of the squared difference between regional vote shares in the monetary policy committee and relative economic size in a given year for the US, Germany, and the euro area. In case of the Federal Reserve, economic size is proxied by population shares until 1977 and GSP shares thereafter.<sup>31</sup>

<sup>30</sup> There are compelling reasons for putting the ECB's design into "historical" perspective by comparing it with the Fed. Still, Thygesen (1989: 91) might go too far when he states that "[i]t seems more instructive to look at the experience of an existing federal banking system which has evolved over the past 75 years than to start from more abstract notions of how such a system might be designed." Without theory, it is hard to tell whether the example set by the Fed provides worthwhile guidance.

<sup>31</sup> There is no straightforward way to pinpoint the voting share of the Board within the various predecessors of the FOMC between 1914 (when the Board held no votes) and the 1930s (when its share converged to today's level). See the [Appendix](#) for a brief synopsis of the Fed's history in this regard and the assumptions on Board voting shares based on this.

The regional vote share has two components. The first component is a region's own vote share in the monetary policy committee. The second reflects the fact that the Board, if Board members take a national perspective when casting their vote, will take regional developments into consideration. Assuming that Board members weigh regional developments according to a region's relative economic size, the second component can be calculated as the product of the Board's voting share and a region's relative economic size. While there is a range of alternative assumptions regarding the Board's voting behavior, the relative results presented in Fig. 3 are quite robust. We will return to this issue below.

A number of stylized facts emerge from Fig. 3. First, misrepresentation is not constant but changes over time, with institutional reform being the driving factor. While some of the developments depicted in Fig. 3 are due to shifts in relative economic size, the most visible changes are clearly determined by institutional innovations.<sup>32</sup> Second, both the Fed and the Bundesbank significantly reduced misrepresentation over time. The institutional reforms that reduced the gap between economic and political weights included, in case of the Fed, the introduction of an asymmetric rotation scheme based on relative economic size in the mid-1930s, and, in case of the Bundesbank, the redrawing of the districts represented in the monetary policy committee in the 1950s and 1990s, which eliminated separate representation for some of the smaller regions. Another factor reducing misrepresentation in both cases was the strengthening of the Board—assuming that Board members are more likely to take a national rather than a regional perspective, increasing its relative vote share will help reducing the mismatch between regional representation in the monetary policy committee and economic size.<sup>33</sup> That is part of what Eichengreen (1992: 14) may have in mind, when he writes that “[t]he early history of the Federal Reserve System... should be read as a cautionary tale. (...) It points to the advisability of reducing existing European central banks to mere branch offices of the ECB or of eliminating them entirely.”<sup>34</sup>

Finally, Fig. 3 clearly identifies the ECB as an extreme case: with the entry of Greece in 2001, the misrepresentation indicator for the ECB's Governing Council reached values about seven times higher than for the Fed's FOMC or the Bundesbank's Zentralbankrat. Without reform, EMU enlargement could lead to even wider gaps between economic and political weights by the 2010s. In the envisaged EMU24 scenario, the misrepresentation index is likely to stay above pre-enlargement levels despite the 2003 reform and, thus, very high relative to the two other federal central banks.<sup>35</sup>

<sup>32</sup> Some of the more important institutional changes are identified in the figure (also see the Appendix). On the history of the Fed, see, for instance, Meltzer (2003), Eichengreen (1992), and Thygesen (1989). On the Bundesbank, see, among others, Bundesbank (1992) and Berger (1997) and the references therein.

<sup>33</sup> That is the assumption underlying Fig. 3—see above.

<sup>34</sup> In fact, the evolution of the Federal Reserve System was characterized by the struggle between federal (or national) and regional forces from the beginning. For instance, H. B. Joy, Director of the Chicago Fed (quoted in Meltzer (2003: 75) exclaimed in 1914: “I have a little feeling—in fact it is growing on me—that the Federal Reserve Board in Washington is inclined toward dominating District Banks.”

<sup>35</sup> In a larger EMU with 27 members that included, in addition, the current opt-outs UK, Sweden, and Denmark, the index *after* reform could end up somewhat below the pre-enlargement level. See Berger (2002, Appendix).

**Table 3** Comparing misrepresentation of economic size in the ECB in 2001

	Federal reserve	Bundesbank	ECB	Ratio ECB/Fed	Ratio ECB/Buba
(1) Board votes with region	0.66	0.91	4.60	7.0	5.1
(2) Board does not vote with region	5.54	5.70	33.33	6.0	5.9
(3) Board without voting rights	3.79	3.24	10.34	2.7	3.2

Source: US Census Bureau, US Bureau of Economic Analysis, US Federal Reserve; German Statistical office, German Bundesbank, Meltzer (2003), and own calculations.

Notes: The table shows the misrepresentation index defined in Fig. 3 under different assumption regarding the behavior of the Board. *Board votes with region* refers to figures resulting under the assumption made in Fig. 3, that is, the weight that the Board attaches to developments in each region is strictly proportional to the regions' relative economic size. *Board does not vote with region* assumes that Board votes are neutral with regard to regions. *Board without voting rights* ignores the Board's votes altogether, computing the regions' voting rights as a share of regional votes only. Bundesbank data refers to 1992, ECB and Fed data to 2001. There is little change in the results if instead 2004 data is used.

Table 3 shows that similar stylized facts emerge under alternative assumptions about the behavior of Board members. In line (1), the table reproduces the misrepresentation index as computed for Fig. 3 for the ECB, the Fed, and the Bundesbank. The assumption is that the Board votes "with" the regions depending on their relative economic size. Alternatively, we could assume that Board members cast their votes completely independent of regional developments [see line (2) for results] or we could simply ignore Board votes altogether in the computation of the misrepresentation index [see line (3)]. As the last two columns in Table 3 reveal, the relative difference between misrepresentation in the ECB on the one hand and Fed and Bundesbank on the other is the largest under assumption (1) and broadly comparable under assumption (2). In these cases, the misrepresentation index within the ECB Governing Board reaches levels that are 5 to 7 times larger. Setting board votes to zero under assumption (3), the relative misrepresentation index for the ECB is lower, but at about three times the level of today's Fed and Bundesbank it still qualifies as extreme.<sup>36</sup>

If the history of the Fed and Bundesbank is any guide, the stark gap between regional representation in the ECB's Governing Board and relative economic size will (and perhaps should) not last. As Fig. 3 illustrates, both federal central bank systems started at levels of misrepresentation comparable to the ECB today, but then worked systematically to reduce the gap between representation and size—not least to avoid some of the problems identified earlier. For instance, for Meltzer (2003) the relatively weak role of the Board pre-1935 within the Fed's monetary policy committee and the continuous struggle between various regional and federal interests were among the key reasons for what many have qualified as a dismal per-

<sup>36</sup> The type of index (e.g., quadratic rather than absolute) may influence the measured distance between institutions as well. However, the fact that the ECB comes out at the higher end compared to both Fed and Bundesbank is independent of the particular index selected.

formance of US monetary policy in the 1920s and 1930s.<sup>37</sup> And the Bundesbank (1992) stressed that the 1992 redistricting ended a period of strong (and not welcome) differences in terms of size and economic significance.<sup>38</sup>

### 3 An Application To the Eurosystem

#### 3.1 Taking Stock: Where Does the ECB Stand Compared To the Benchmark?

The discussion in Section 2 establishes certain benchmarks (however crude) that help us to broadly characterize efficient central bank design. First, the *optimal size* of a monetary policy committee should be a moderately large number. There is theoretical and experimental evidence implying that single-person committees are not efficient, but decision-making costs are likely to be convex in the number of committee members. This suggests that the optimally sized monetary policy committee is larger than one but not too large. Taking a cue from the (unconditional) average of central bank governing bodies, a reasonable upper bound seems to be around 10 for centralized central banks and around 20 for federal central bank systems, which the latter number backed by a significantly smaller number of examples. Taking the federal underpinnings of the Eurosystem as given, the relevant upper bound for the ECB's Governing Board would be around 20. The arguments regarding the *optimal degree of centralization* (i.e., ratio between Board and regional representatives) are involved, but, in general, theory suggests striking a balance between regional (or sectoral) and centralized components. For instance, one advantage of a high vote share for the centrally appointed Board is that it may help ensuring the area-wide perspective of monetary policy; disadvantages include possible limits to the central bank's factual independence from the political center and reduced access to regional information. Empirically, however, perhaps reflecting a higher degree of political and economic heterogeneity, it is mostly the federal central bank systems that are characterized by an interior solution. The majority of monetary policy committees are fully centralized. The share allocated to regional representatives in the Bundesbank and Fed systems is in the 40–50% range. Finally, given a share of regional representation, the *optimal degree of representation* of relative economic size is an issue. Balancing the trade-off, theory suggests that neither “one region, one vote” nor voting-rights fully attuned to, say, GDP shares may be optimal. More equal voting rights allow moderating policy regional preference shocks, but, at the same time, could lead to regional interests dominating aggregate monetary policy. This qualitative result is broadly in line with the fact that both Bundesbank and Fed show a non-zero degree of misrepresentation—but their example (both significantly

<sup>37</sup> Based on Meltzer's (2003) detailed account, this includes tensions between different regions regarding their differing representation in the FOMC and its predecessors. For an assessment of the Fed's performance see, famously, Friedman and Schwartz (1963) and Eichengreen (1992).

<sup>38</sup> The Bundesbank had inherited these differences from the Bank Deutscher Länder, its predecessor set up under Allied government in the late 1940s. In 1957, German law makers, while debating problems associated with this setup, had refrained from redistricting. See Bundesbank (1992).

reduced the level of misrepresentation over time) also suggest that much higher degrees may be too extreme.

At present, the ECB looks broadly in line with two out of three benchmarks. With currently 18 members, the ECB's Governing Council is about en par with the pre-1999 Zentralbankrat and the number of participating (if not voting) FOMC members. Of course, the Governing Council is much larger than the average central bank decision-making body, but so are the two other federal monetary policy committees. Looking at centralization, the ECB stands out somewhat more. At about 66%, the vote share commanded by regional representatives in the Governing Council clearly exceeds the ones in Bundesbank and Federal Reserve. The most striking difference between these three banks occurs regarding the representation-benchmark, however. As elaborated earlier, the degree of misrepresentation of economic size by regional voting rights is a stunning 3–7 times larger than in Fed or Bundesbank, depending on the assumptions made concerning the voting behavior of Board members (see Table 3). In other words, the "one country, one vote" principle currently enforced within the Governing Council renders the ECB an extreme case—arguably, with possible consequences for a balanced representation of the euro area.

Euro area enlargement is set to further increase the distance to the benchmark. As discussed in Section 2, in a hypothetical EMU with 24 members (including the ten recent EU entrants, as well as Bulgaria and Rumania) without reform, the size of the ECB Governing Council (30 members), the share of regional voting rights (80%), and the degree of misrepresentation (even larger than today—see Fig. 3) within the Eurosystem would by far exceed the levels present in the pre-1999 Bundesbank or today's Federal Reserve System.

The 2003 reform of the ECB statute will moderate but not reverse the impact of enlargement. First, the reform will limit the number of voting members to 15 (out of 24) national central bank representatives and six Board members—even though all 30 might participate in Governing Board meetings. Second, the reform will moderate the decline in the degree of centralization, with regional representatives holding about 70% of voting rights (but about 80% of seats) in the Governing Council. Finally, the introduction of the asymmetric rotation system will reduce the degree of misrepresentation in the EMU24 scenario to levels only moderately higher than at present. Clearly, however, while the 2003 reform works in the right direction, it will only partially compensate the effects of enlargement (at least in the scenario considered here), leaving the ECB farther away from the benchmark along all three dimension than already today. There is, in short, room for improvement.

### 3.2 Principle Alternatives for Further ECB Reform

The book on ECB reform might not be closed. Even though, as Servais (2006) reports, the 2003 ECB reform has been ratified by all member countries and is scheduled to be implemented in two stages as EMU membership increases (ECB, 2003), some open issues remain and are likely to require further attention. For instance, the particularities of the asymmetric rotation scheme imply an unintended discontinuity in the difference between the voting frequencies of large and medium-sized countries in the Governing Council when EMU membership increases from 18

**Table 4** Alternative ECB reform scenarios

Alternative scenarios	Size	Centralization	Representation	Plausible?
<b>(1) Substitute rotation:</b>				
(a) IMF-style representation: equal-sized groups of CBs with restricted mandate	Very large (de facto)	Low	Close(r) to proportional	Unlikely, at least de jure
(b) Buba-style redistricting: redistricted regional CBs of similar economic size	Possibly optimal	Low	Close(r) to proportional	Unlikely, at least de jure, in the short-run
(c) EU-style weighted voting: size-weighted governor votes, all participate	Very large (de facto)	Low	Proportional	Unlikely
<b>(2) Move to full centralization:</b> decision power rests with Board alone	Small	Very high	Proportional via Board	Unlikely
<b>(3) Fine-tune reform:</b> more asymmetric rotation; larger Board, fewer governors	Very large (de facto)	Optimal	Close(r) to proportional	Perhaps

to 19.<sup>39</sup> And, more generally, the introduction of new members to the euro area might lead to additional debates regarding, among other things, the way member countries are size-ranked and allocated rotation frequencies. Finally, looking back at the dynamics of central bank design in the US and Germany, there is little reason to expect that any central bank statute is cast in stone—especially when potential inefficiencies are looming.

What are options for (further) ECB reform and how do they compare against the benchmarks discussed above? Table 4 gives a brief overview over some of the possibilities.<sup>40</sup>

One option would be to substitute the planned rotation scheme by alternative setups that aim at reducing the mismatch between political and economic weights of regional governors in the Governing Council. For instance, *IMF-style representation* would have economically equal-sized groups of countries be represented by one governor in the Governing Council. While this arrangement would reduce the de jure-size of the decision-making committee, it would not necessarily reduce decision making costs. This is because, if the mandates of group representatives were restricted, regional governors will indirectly participate in the decision-making process at the group level. Moreover, even if the overall number of groups was roughly in line with today's setup (i.e., twelve), the resulting degree of centralization within the Governing Board would remain low.

<sup>39</sup> At this point, the difference in voting frequency drops from 23 percentage points to 1, but increases again to 7 and 11 percentage points with 20 and 21 members (see ECB, 2003). One solution would be to force countries to join EMU in groups rather than individually.

<sup>40</sup> This discussion mirrors, in part, the debate on the 2003 ECB reform. For an overview see, among others Berger et al. (2004), de Haan et al. (2004) and the literature quoted therein.

*Bundesbank-style redistricting* of national central bank regions to create districts of more equal economic size, another principle substitute for rotation, has the potential to help reducing decision-making costs compared to the representation scheme.<sup>41</sup> However, to avoid the problem of a simple reallocation of decision-making costs to the regional level, the “one region (or country), one vote” principle would have to be given up—that is, representatives of countries forced into one district could not be allowed to determine the behavior of the district’s representative in the Governing Board. Similar to representation, the degree of centralization resulting from redistricting depends on the resulting number of districts. *EU-style weighted voting*, too, has the potential to reduce misrepresentation of economic size. Weighting the votes of Governing Council members would all but guarantee that any formal decision represents the economic interest of the euro area. As with representation, however, decision making costs are likely to remain high, if actual decision-making continued to involve elements of the consensus approach. Moreover, absent a simultaneous increase in the number of voting Board members, the degree of centralization would remain low.

A second principle option, popular with many observers prior to the 2003 ECB reform, remains *full centralization*. Bringing the ECB to the main stream of central bank design would require giving up the existing federal structure, which would constitute an even more radical departure from the status quo than substituting the envisaged rotation scheme. The advantages of a fully centralized solution include the likely absence of a regional bias in decision-making and low decision-making costs. A possible disadvantage (not captured in Table 4, but highlighted in Section 2.2) could be a reduction in factual independence due to the absence of checks and balances.

Perhaps the greatest problem with the reform scenarios discussed so far is that their chances of being implemented are, at best, modest. This is particularly true for the centralization option, which runs against the organizational principle underlying most other European institutions and would require EMU member countries giving up even the last iota of influence on ECB policy after having given up monetary sovereignty for a seat in the Governing Council.<sup>42</sup> Differentiating between schemes to substitute rotation, weighted voting is perhaps the least plausible option because it does achieve little more than the envisaged rotation system, and rotation is seen as more compatible (at least in formal terms) with the idea that each member casts “one vote” (ECB, 2003). In comparison, redistricting and representation seem somewhat more likely to be implemented—if not formally, than perhaps on a factual basis. Redistricting could be a natural longer-run solution to the strains the ever increasing demands of full-scale membership in the Eurosystem put on smaller member countries.<sup>43</sup> Similar forces could lead to the factual introduction of elements of representation within the

<sup>41</sup> If the number of districts was close to today’s EMU membership, the overall size of the Governing Council would remain on today’s level and, thus, broadly in line with the benchmark discussed in Section 2.1.

<sup>42</sup> Berger et al. (2004) make a similar point.

<sup>43</sup> For instance, Lindner (2006) reports that between 1996 and 2003 the number of required trips of Austrian central bank staff to Frankfurt has more than doubled to more than 600 a year.

envisaged rotation scheme (for instance, by smaller countries collectively organizing meeting-preparation or even voting).

The most likely further reform effort, however, is probably a *fine-tuning of the rotation scheme* setup—and this might not be a bad thing. This could take the form of a reduction of the regional component through a decrease in the governors' vote share in favor of the Board and a more asymmetric allocation of voting rights among regional representatives (either by changing the allocation of votes to country groups or by increasing the number of groups) to reduce misrepresentation. A further reduction in the number of Governing Council seats in an attempt to limit decision-making costs would also be conceivable, but, as with representation and weighted-voting, the impact on actual decision-making costs would depend on the Governing Council's willingness to enforce decision-making by vote and forgo consensus-based practices involving all members. Nevertheless, fine-tuning may have the potential to bring the ECB closer to the benchmark at least in two out of three areas (i.e., centralization and representation). In that sense, the most likely approach to further ECB reform might very well be among the more promising ones in efficiency terms.

#### 4 Concluding Remarks

The organizational underpinnings of monetary policy-making tend to change slowly, but they do change—and often for good reasons. Like the US Fed in the 1930s and the German Bundesbank in the 1990s, the European Central Bank has recently adjusted the design of its monetary policy committee. In case of the ECB, these changes were pre-emptive, anticipating the enlargement of the European Economic and Monetary Union; the Bundesbank reacted to German unification, and the reforms of the FOMC reflected, in part, what many considered a less-than-optimal performance of the Fed during the Great Depression. In all cases, however, the ultimate goal of reform was ensuring the efficiency of decision-making.

But what exactly should we be looking for in optimal central bank design? The present paper highlights three basic topics: the question of how many people should be responsible for monetary policy decision; the issue of how much weight should be given to central and regional representation in the monetary policy committee; and the problem of identifying the degree to which regions should be represented in such a committee based to their economic weight. In addition to being at the core of a still growing literature on optimal central bank design, these topics were also at the center of debate when the ECB proposed to change its statute in 2003.

Combining theoretical arguments with empirical evidence on the actual structure of central banks, a benchmark (however rough) for optimal central bank design emerges. (i) Regarding size, there is theoretical and experimental evidence suggesting that single-person committees are not efficient, but decision-making costs are likely to be convex in committee members. Based on the (unconditional) average of central bank governing bodies, a reasonable upper bound for committee size seems to be around 20 for federal central bank systems such as the ECB. (ii) The trade-off behind the optimal degree of centralization balances, among other

things, the wish to ensure an area-wide perspective with possible repercussions for central bank independence and better access to regional information. Empirically, a strong regional presence is the exception rather than the rule, and even within federal central bank systems such as the Bundesbank and Fed, regional representatives do not hold much more than 50% of the available votes. (iii) As to the optimal degree of representation of relative economic size, theory suggests that equal voting rights might help moderating regional preference shocks, but at the possible price of allowing regional interests to dominate monetary policy. That both the Bundesbank and Fed significantly reduced the gap between regional voting rights and relative economic size over time suggests that much higher degrees may be too extreme.

While there are some obvious caveats to this kind of reasoning, applying the resulting benchmarks to the ECB can be instructive.<sup>44</sup> The paper finds the current design of the ECB to be broadly in line with recommendations, with the possible exception of a relative high mismatch between relative economic size and regional voting rights in the Governing Council. However, the picture changes once EMU enlargement is taken into account. Even when factoring in the effects of the 2003 ECB reform—the reform establishes an upper limit for committee size and introduces an asymmetric rotation (and this voting) scheme that favors larger regions in case of enlargement—the ECB might be significantly “off” the benchmark once EMU membership increases. For instance, in a scenario with 24 euro area members (including the new EU entrants as well as Bulgaria and Rumania), up to 30 decision-makers might participate in Governing Board meetings, the voting share of regional representatives would reach about 70%, and the degree of misrepresentation of relative economic size will be at least three times the level at the Fed or the pre-1999 Bundesbank.

Against this background, a refinement of the planned asymmetric rotation scheme would have advantages. Such fine-tuning could reduce the relative vote share of regional (i.e., national) governors in favor of the Board and, in addition, adjust regional voting rights to better reflect relative economic size and reduce misrepresentation. In addition, a further reduction in the number of Governing Council seats could help to limit decision-making costs, even though the effect of such a measure would, in part, depend on the ECB’s willingness to forgo consensus-based practices involving all members present. An added advantage of fine-tuning the current design of the ECB’s monetary policy committee along these lines would be that it follows the pattern of the 2003 reform. This might enhance its feasibility in political terms compared to more radical proposals such as UK-style full centralization of euro area monetary policy.

**Acknowledgments** I would like to thank the OeNB for its hospitality and Carsten Hefeker, Till Müller, Volker Nitsch, Nathan Sheets, and an anonymous referee for helpful comments and suggestions.

---

<sup>44</sup> First, these benchmarks are based on theoretical arguments that are, more often than not, qualitative and, therefore, hard to translate into hands-on guidelines for institutional design. In addition, where empirical results have been used, these stylized facts are descriptive rather than based on an explicit analysis of determinants of central-banking success.

## Appendix

## A (Brief) Synopsis of the Role of the Board in the Fed's Monetary Policy Committee

Name	Year	Banks	Board	Sum	Share Banks	Comments
Governors Conference	1914	12	5+2	19	100	Board with 5 members from districts (not 2 out of 1), 2 government members (Secretary of the Treasury, Comptroller of the Currency). Law stipulates that <i>authority for open market policy rests solely with regional Federal Reserve Banks</i> , which are more interested in earnings than national monetary policy concerns. As a consequence, the <i>possibility to opt out of coordinated open market policies</i> remains intact (while gradually reduced) until Banking Act of 1935: " <i>local option</i> ."
Committee on Centralized Purchases and Sales	1922	5	5+2	12	100	CCPS coordinates Reserve Bank open market actions, makes suggestions. <i>Fed NY emerges as dominant force</i> , while taking into account the interest of other Federal Reserve Banks—not least to keep the Board at bay. Participation of Reserve Banks in the suggested open market actions remains voluntary, though.
Open Market Investment Committee (1)	1923	5	6+2	13	~90	Agricultural interests gain a seat in the Board. Board forces abolition of CCPS, renaming it OMIC, and trying to put it under Board authority. While the GC rejected this, the <i>Board gained some supervisory power</i> over open market operations. Before that point, such power only existed with regard to discount rate decisions. Still, participation of Reserve Banks in the coordination of open market policy remained voluntary.

Open Market Investment Committee (2)	1928	12	6+2	20	~85	Board succeeded in <i>reducing the power of the FedNY</i> by making the original OMIC responsible to all Federal Reserve Banks; the original OMIC continued as an executive committee
Open Market Policy Conference	1930	12	6+2	20	~80	Name change mainly the result of a bungled attempt by the <i>Board to gain veto power over open market policy</i> decisions by the Federal reserve banks (similar to discount policy). Little else changed. For instance, the Federal Reserve Banks on Chicago and Boston often abstain from coordinated open market operations. (Benjamin Strong, dominant Governor of the NYFed, died earlier.)
Federal Open Market Committee (1)	1933	12	6+2	20	~70	Similar to OMPC in all but its name (Banking Act of 1933). <i>Board gains some powers</i> of Federal Reserve Banks, including wider supervisory powers on open market operations. However, Federal Reserves still had a "local option." Chicago, for example, made use of this in 1933 (the suggested purchases threatened profits)
Federal Open Market Committee (2)	1935	5	7	12	42	<i>Asymmetric representation scheme</i> for the 5 Reserve Bank seats (1 representative selected each year, no rotation). Board no without ex officio government members, but reduced by 1 to 7
Federal Open Market Committee (3)	1942	5	7	12	42	<i>Asymmetric rotation scheme</i> for the 5 Reserve Banks. Groups changed from 1935
